' R Q ¶ W ZDLW DQ\PRUH An Answer:
An experiment with actual organ donor registrations

By Judd B. Kessler and Alvin E. Roth[Á]

This Draft: February 21, 2013

ABSTRACT

We experimentally investigate how individuals respond to an opportunity to change their actual Massachusetts organ donor registration status. Many unregistered individuals join the registry (29%) while almost all registered individuals remain (99%). How individuals are asked impacts the decision. Contrary to a popular hypothesis, ³ P D Q G D W H G F K R L F H ´ frame that forces individuals to choose either yes or no does not increase registration U D W H V R Y H U D Q D O W H U Q D W L Y H Z K L F K S H R S O H F K H F N D E R [W R U not to register. A second experiment suggests W K D W ³ P D Q G D W H G F L J D U H W W H V ´ D O V R

I.

One potential strategy to encourage organ do

o

completing a survey.[12] Subjects were not informed in advance, however, that organ donation was the subject being studied.

Once they arrived at the laboratory, each subject was seated at an isolated computer terminal and provided with a consent form. The consent form indicated what subjects would do in the research study. To ensure subjects understood, the experimenter read one paragraph from the consent form aloud to all subjects. This paragraph read:

"What you will do in this research: You will (1) enter information that will be used to log you into a registry of organ and tissue donors in Massachusetts, (2) be provided with information about organ and tissue donation, (3) decide whether or not you would like to U H J L V W H U D V D Q R U J D Q D Q G W L V V X H A p p e n d i x B for D Q G F R R the full consent form.)

After signing the consent forms, subjects initiated the study by logging into the Massachusetts Organ and Tissue Donor Registry maintained by th9(Tis9nt p)-9(a)4(st)83(mnut fr)

III.

III.1 Asking again for organ donation

Table 1 provides demographic information about the 368 subjects who participated in the study as collected in the survey conducted after the registration decision. For each demographic breakdown, we show the percentage of those subjects who were donors before they entered the lab and those who were donors when they left. In the "PR test p-value" column, we denote the p-value associated with a two-sample test of proportions and indicate whether the change in percentage of registered (ted)] TJ ET BT 1 0 044 299.1

t(whex3( )4(pe)imen(or) indi)s sin tisiea4(ol(I)20(y)20( )] TJ ET BT 1 0 0 3 691028 522.9 Tm 4(is

Result 2: People who are given the opportunity to change their organ donor registration status overwhelmingly add themselves to the registry and do not remove themselves from the registry.

The increase in the number of donors highlighted in Result 1 was driven by both: (1) previous non-donors adding themselves to the registry and (2) previous donors keeping themselves on the registry. When given the opportunity to change their organ and tissue donor registration status, current donors were very unlikely to remove themselves from the registry (the 1.3% probability of removal from the registry is not statistically significantly different from 0; two-sided *t*-test, $p > 0.1$). Previous non-donors, however, were quite likely to add themselves to the organ and tissue donor registry (the 28.8% probability of joining the registry is statistically and economically significant). These results suggest that the intention to register as a donor appears to be stable, while the intention not to register appears to be less stable.

These results are relevant for policy in that they suggest that an individual being listed on a state registry or having a heart or an organ donor signature on his or her driver's license reflects his current intent to be a donor. This is an important fact for the Anatomical Gift Act, which says that these intention measures can be used to reflect the last wishes of a deceased donor (Glazier et al. 2009).

Furthermore, Glazier (2006) has suggested that an online registry from which one can at any time make changes to one's donation decision would make it easier to donate clearer. One might

High School	30	8%	13	36	0.037**
Some College					

Finally, the results on Table 2 show that this effect of giving subjects the opportunity to change their organ registration status leading to more registered donors is not being driven by any particular subgroup. Table 2 breaks the experimental subjects down by demographic characteristics identified in our survey. We find directionally positive effects for every subgroup with more than 14 subjects and positive and statistically significant effects for every subgroup of more than 75 subjects.

The opt-in frame where a subject simply checks the box

IV.1 Design

The survey ([SHULPHQW ZDV UXQ ZLWK VXEMHFWV UHFUXLWHG IURP Amazon's Mechanical Turk platform on January 8, 2013. Subjects were told the survey would take 5 to 10 minutes (on average it was completed in just over 5 minutes). Subjects were paid $0.50 for completing the survey, a relatively large compensation for a 10 minute survey on Mechanical Turk.

In the survey, subjects were asked about what a hypothetical next of kin should do with regards to donating the organs of a recently deceased relative. The subjects were asked to make decisions about four scenarios, presented one-at-a-time in one of four random orders. All scenarios began in the same way. Subjects read:

"An individual has died. The individual's next of kin has been asked whether or not they would like to donate the organs of the deceased. The only information that the next of kin has about the wishes of the deceased is that the deceased saw this screen..."

Subjects were then

with the same decision frame but the opposite decision by the deceased (e.g. if they first answered TXHVWLRQV DERXW D GHFHDVHG ZKR ³VHOHFWHG µ, WLVVXH GRQ¶W UHJLVWHU DQG WKH\ ZHUH WKHQ DVNHG DERXW D VHOHFW µ, ZDQW WR UHJLVWHU DV DQ RUJDQ DQG WLVVX

After answering both questions for one frame, they answered the questions for two more scenarios with decisions being made by next of kin under the other frame. For VLPSOLFLW\ WKH RUGHU RI WKH GHFHDVHG¶V GHFLVLRQ kept the same for each frame (e.g. if subjects had been asked about a deceased who joined the registry in the first scenario, they were asked about a deceased who joined the registry in the third scenario). This generated four orders of scenarios. Subjects were randomly assigned to one of these four orders.

7R VXPPDUL]H first scenario was hypothetical and the deceased was chosen to be either: (1) a deceased who joined the registry in an opt-in frame, (2) a deceased who had not joined the registry in an opt-in frame, (3) a deceased who joined the registry in a mandated choice frame, or (4) a deceased who had not joined the registry in a mandated choice frame. Subjects then saw the opposite decision by the deceased in the same frame, the saw the first decision by the deceased in the other frame, and finally saw the opposite decision of the deceased in the other frame.

IV.2 Results

The design of the experiment allows for both a between-subject analysis of the next-of-kin questions (comparing answers from the first scenario a subject saw) and a within-subject analysis (comparing how the same subject responded to the deceased making the decision to join ³ or not join ² the registry under different frames). We discuss the between-subject results first.

Result 5: Subjects think the next of kin should donate organs of an unregistered deceased more often when the deceased did not opt-in than when the deceased declined to register under mandated choice.

Table 5 reports the percent of subjects who said the next of kin should donate the organs of the deceased as well as their confidence on a 7-point scale with mean 0 constructed from the confidence answers.[25] When the deceased was not on the registry because the deceased had not opted in, 38.1% of subjects stated that the next of kin should donate the organs. When the deceased was not on the registry because they

[25] 7KH VFDOH UDQJHV IURP ³YHU\ FRQILGHQW WKDW WKH next of kin should donate´ WR ³YHU\ FRQILGHQW WKDW WKH next of kin should not donate´ with 0 being equal to 3.5, DQG ³YHU\ FRQILGHQW´ WKH QH[W RI NLQ VKRXOG GRQDWH ZLWK D XQLW MXPS VKRXOG GRQDWH´ WR ³YHU\ FRQILGHQW´ WKH QH[W RI NLQ VKRXOG QRW GRQDWH´ ZLWK D XQLW MXPS

indicated they did not want to register under a mandated choice frame, only 26.7% of subjects thought next of kin should donate. This 11.4 percentage point difference is statistically significant (t-test, 803 observations, p<0.05) and represents a 43% increase (on the base of 26.7 percent) in the number of subjects who say the next of kin should donate the organs of the deceased. Subjects are much more hesitant about donating the organs of a deceased who indicated that they did not want to be a donor in a mandated choice frame than a deceased who simply did not chose to opt to become a donor.

Table 5:

deceased was asked to register as a donor without a major experimental manipulation of state policy (followed by a long wait for people to die and next of kin to make organ donation decisions). Consequently we think it is reasonable to start the process with experimental survey data that can provide guidance about how individuals might respond to state policies and what policy might be best.[27]

V.

actual donor registration decisions, which may explain some of the difference from previous papers that rely on hypothetical decisions. Second, we do not vary the default for organ donation in Massachusetts (as is varied in the hypothetical scenarios of Johnson and Goldstein 2003, 2004). We just vary how individuals are asked to register. Given that our experiment does not find a benefit of mandated choice on registration rates, it is particularly worrisome that subjects believe
